#### Abstract

Let $M$ be an orientable hypersurface in the Euclidean space $R^{2 n}$ with induced metric $g$ and $T M$ be its tangent bundle. It is known that the tangent bundle $T M$ has induced metric $\bar{g}$ as submanifold of the Euclidean space $R^{4 n}$ which is not a natural metric in the sense that the submersion $\pi:(T M, \bar{g}) \rightarrow(M, g)$ is not the Riemannian submersion. In this paper, we use the fact that $R^{4 n}$ is the tangent bundle of the Euclidean space $R^{2 n}$ to define a special complex structure $\bar{J}$ on the tangent bundle $R^{4 n}$ so that $\left(R^{4 n}, \bar{J},\langle\rangle,\right)$ is a Kaehler manifold, where $\langle$,$\rangle is the$ Euclidean metric which is also the Sasaki metric of the tangent bundle $R^{4 n}$. We study the structure induced on the tangent bundle ( $T M, \bar{g}$ ) of the hypersurface $M$, which is a submanifold of the Kaehler manifold $\left(R^{4 n}, \bar{J},\langle\rangle,\right)$. We show that the tangent bundle $T M$ is a CR-submanifold of the Kaehler manifold $\left(R^{4 n}, \bar{J},\langle\rangle,\right)$. We find conditions under which certain special vector fields on the tangent bundle $(T M, \bar{g})$ are Killing vector fields. It is also shown that the tangent bundle $T S^{2 n-1}$ of the unit sphere $S^{2 n-1}$ admits a Riemannian metric $\bar{g}$ and that there exists a nontrivial Killing vector field on the tangent bundle (TS $\left.{ }^{2 n-1}, \bar{g}\right)$.

Keywords: Tangent bundle, Hypersurface, Kaehler manifold, Almost contact structure, Killing vector field, CR-Submanifold, Second fundamental form, Wiengarten map.

## 1. Introduction

Recently efforts are made to study the geometry of the tangent bundle of a hypersurface $M$ in the Euclidean space $R^{n+1}$ (cf. [3]), where the authors have shown that the induced metric on its tangent bundle $T M$ as submanifold of the Euclidean space $R^{2 n+2}$ is not a natural metric. In [4], we have extended the study initiated in [3] on the geometry of the tangent bundle $T M$ of an immersed orientable hypersurface $M$ in the Euclidean space $R^{n+1}$. It is well known that Killing vector fields play an important role in shaping the geometry of a Riemannian manifold, for instance the presence of nonzero Killing vector field on a compact Riemannian manifold forces its Ricci curvature to be nonnegative and this in particular implies that on a compact Riemannian manifolds of negative Ricci curvature there does not exist a nonzero Killing vector field. The study of Killing vector fields becomes more interesting on the tangent bundle $T M$ of a Riemannian manifold $(M, g)$ as the tangent bundle $T M$ is noncompact. It is known that if the tangent bundle $T M$ of a Riemannian manifold $(M, g)$ is equipped with Sasaki metric, then the verticle lift of a parallel vector field on $M$ is a Killing vector field (cf. [15]). However if the Sasaki metric is replaced by the Cheeger-Gromoll metric, then the vertical lift of any nonzero vector field on $M$ is never Killing (cf. [14]). Note that both Sasaki metric as well as Cheeger-Gromoll metrics are natural metrics. We consider an orientable real hypersurface $M$ of the Euclidean space $R^{2 n}$ with the induced metric $g$. Then as the tangent bundle $T M$ of $M$ is a submanifold of codimension two in $R^{4 n}$, it has induced metric $\bar{g}$ and this metric $\bar{g}$ on $T M$ is not a natural metric as the submersion $\pi:(T M, \bar{g}) \rightarrow(M, g)$ is not the Riemannian submersion (cf. [3]). Let $N$ be the unit normal vector field to the hypersurface $M$ and $J$ be the natural complex structure on the Euclidean space $R^{2 n}$. Then we have a globally defined unit vector field $\xi$ on the hypersurface given by $\xi=-J N$ called the characteristic vector field of the real hypersurface (cf. $[1,2,5,6,7,8,9]$ ), and this vector field $\xi$ gives rise to two vector fields $\xi^{h}$ (the horizontal lift) and $\xi^{v}$ (the vertical lift) on the tangent bundle $(T M, \bar{g})$. In this paper, we use the fact that $R^{4 n}$ is the tangent bundle of the Euclidean space $R^{2 n}$ and that the projection $\bar{\pi}: R^{4 n} \rightarrow R^{2 n}$ is a Riemannian submersion, to define a special almost complex structure $\bar{J}$ on the tangent bundle $R^{4 n}$ which is different from the canonical complex structure of the Euclidean space $R^{4 n}$ and show that $\left(R^{4 n}, \bar{J},\langle\rangle,\right)$ is a Kaehler manifold, where $\langle$,$\rangle is the Euclidean metric$ on $R^{4 n}$. It is shown that the codimension two submanifold $(T M, \bar{g})$ of the Kaehler manifold $\left(R^{4 n}, \bar{J},\langle\rangle,\right)$ is a CR-submanifold (cf. [10]) and it naturally inherits certain special vector fields other than $\xi^{h}$ and $\xi^{v}$, and in this paper we are interested in finding conditions under which these special vector fields are Killing vector fields on $(T M, \bar{g})$. One of the interesting outcome of this study is, we have shown that the tangent bundle $T S^{2 n-1}$ of the unit sphere $S^{2 n-1}$ as
submanifold of $R^{4 n}$ admits a nontrivial Killing vector field. It is worth pointing out that on the tangent bundle $T S^{2 n-1}$ with Sasakian metric no vertical or horizontal lift of a vector field is Killing as this will require the corresponding vector field on $S^{2 n-1}$ is parallel which is impossible as $S^{2 n-1}$ is space of constant curvature 1. Note that on even dimensional Riemannian manifolds which are irreducible, it is difficult to find Killing vector fields, where as on products like $S^{2 k-1} \times S^{2 l-1}, S^{2 k-1} \times R^{2 l-1}, R^{2 k-1} \times R^{2 l-1}$ one can easily find Killing vector fields. Since the tangent bundle $T S^{2 n-1}$ is trivial for $n=1,2$, 4 , finding Killing vector fields is easy in these dimensions, but for $n \geq 5$, it is not trivial.

## 2. Preliminaries

Let $(M, g)$ be a Riemannian manifold and $T M$ be its tangent bundle with projection map $\pi: T M \longrightarrow M$. Then for each $(p, u) \in T M$, the tangent space $T_{(p, u)} T M=\mathfrak{H}_{(p . u)} \oplus \mathfrak{V}_{(p, u)}$, where $\mathfrak{V}_{(p, u)}$ is the kernel of $d \pi_{(p, u)}: T_{(p, u)}(T M) \longrightarrow$ $T_{p} M$ and $\mathfrak{H}_{(p . u)}$ is the kernel of the connection map $K_{(p, u)}: T_{(p, u)}(T M) \longrightarrow$ $T_{p} M$ with respect to the Riemannian connection on $(M, g)$. The subspaces $\mathfrak{H}_{(p . u)}, \mathfrak{V}_{(p, u)}$ are called the horizontal and vertical subspaces respectively. Consequently, the Lie algebra of smooth vector fields $\mathfrak{X}(T M)$ on the tangent bundle $T M$ admits the decomposition $\mathfrak{X}(T M)=\mathfrak{H} \oplus \mathfrak{V}$ where $\mathfrak{H}$ is called the horizontal distribution and $\mathfrak{V}$ is called the vertical distribution on the tangent bundle $T M$. For each $X_{p} \in T_{p} M$, the horizontal lift of $X_{p}$ to a point $z=(p, u) \in T M$ is the unique vector $X_{z}^{h} \in \mathfrak{H}_{z}$ such that $d \pi\left(X_{z}^{h}\right)=X_{p} \circ \pi$ and the vertical lift of $X_{p}$ to a point $z=(p, u) \in T M$ is the unique vector $X_{z}^{v} \in \mathfrak{V}_{z}$ such that $X_{z}^{v}(d f)=X_{p}(f)$ for all functions $f \in C^{\infty}(M)$, where $d f$ is the function defined by $(d f)(p, u)=u(f)$. Also for a vector field $X \in \mathfrak{X}(M)$, the horizontal lift of $X$ is a vector field $X^{h} \in \mathfrak{X}(T M)$ whose value at a point $(p, u)$ is the horizontal lift of $X(p)$ to $(p, u)$, the vertical lift $X^{v}$ of $X$ is defined similarly. For $X \in \mathfrak{X}(M)$ the horizontal and vertical lifts $X^{h}, X^{v}$ of $X$ are uniquely determined vector fields on $T M$ satisfying

$$
d \pi\left(X_{z}^{h}\right)=X_{\pi(z)}, K\left(X_{z}^{h}\right)=0, d \pi\left(X_{z}^{v}\right)=0, K\left(X_{z}^{v}\right)=X_{\pi(z)}
$$

Also, we have for a smooth function $f \in C^{\infty}(M)$ and vector fields $X, Y \in$ $\mathfrak{X}(M)$, that $(f X)^{h}=(f \circ \pi) X^{h},(f X)^{v}=(f \circ \pi) X^{v},(X+Y)^{h}=X^{h}+Y^{h}$ and $(X+Y)^{v}=X^{v}+Y^{v}$. If $\operatorname{dim} M=m$ and $(U, \varphi)$ is a chart on $M$ with local coordinates $x^{1}, x^{2}, \ldots, x^{m}$, then $\left(\pi^{-1}(U), \varphi\right)$ is a chart on $T M$ with local coordinates $x^{1}, x^{2}, \ldots, x^{m}, y^{1}, y^{2}, \ldots, y^{m}$, where $x^{i}=x^{i} \circ \pi$ and $y^{i}=d x^{i}$, $i=1,2, \ldots, m$.

A Riemannian metric $\bar{g}$ on the tangent bundle $T M$ is said to be natural metric with respect to $g$ on $M$ if $\bar{g}_{(p, u)}\left(X^{h}, Y^{h}\right)=g_{p}(X, Y)$ and $\bar{g}_{(p, u)}\left(X^{h}, Y^{v}\right)=0$, for all vectors fields $X, Y \in \mathfrak{X}(M)$ and $(p, u) \in T M$, that is the projection map $\pi: T M \longrightarrow M$ is a Riemannian submersion.

Let $M$ be an orientable hypersurface of the Euclidean space $R^{2 n}$ with immersion $f: M \longrightarrow R^{2 n}$ and $T M$ be its tangent bundle. Then as $F=d f:$ $T M \longrightarrow R^{4 n}=T R^{2 n}$ is also an immersion, $T M$ is an immersed submanifold of the Euclidean space $R^{4 n}$. We denote the induced metrics on $M, T M$ by $g, \bar{g}$ respectively and the Euclidean metric on $R^{2 n}$ as well as on $R^{4 n}$ by $\langle$,$\rangle .$ Also, we denote by $\bar{\nabla}, \bar{\nabla}, D$ and $\bar{D}$ the Riemannian connections on $M, T M$, $R^{2 n}$, and $R^{4 n}$ respectively. Let $N$ and $S$ be the unit normal vector field and the shape operator of the hypersurface $M$. For the hypersurface $M$ of the Euclidean space $R^{2 n}$ we have the following Gauss and Weingarten formulae

$$
\begin{equation*}
D_{X} Y=\bar{\nabla}_{X} Y+\langle S(X), Y\rangle N, D_{X} N=-S(X), \quad X, Y \in \mathfrak{X}(M) \tag{2.1}
\end{equation*}
$$

where $S$ is the shape operator (Weingarten map). Similarly for the submanifold $T M$ of the Euclidean space $R^{4 n}$ we have the Gauss and Weingarten formulae

$$
\begin{equation*}
\bar{D}_{E} F=\bar{\nabla}_{E} F+h(E, F), \bar{D}_{E} \bar{N}=-\bar{S}_{\bar{N}}(E)+\bar{\nabla}_{E}^{\perp} \bar{N} \tag{2.2}
\end{equation*}
$$

where $E, F \in \mathfrak{X}(T M), \bar{\nabla}^{\perp}$ is the connection in the normal bundle of $T M$ and $\bar{S}_{\bar{N}}$ denotes the Weingarten map in the direction of the normal $\bar{N}$ and is related to the second fundamental form $h$ by

$$
\begin{equation*}
\langle h(X, Y), \bar{N}\rangle=\bar{g}\left(\bar{S}_{\bar{N}}(X), Y\right) \tag{2.3}
\end{equation*}
$$

Also we observe that for $X \in \mathfrak{X}(M)$ the vertical lift $X^{v}$ of $X$ to $T M$, as $X^{v} \in \operatorname{ker} d \pi$, where $\pi: T M \rightarrow M$ is the natural submersion, we have $d \pi\left(X^{v}\right)=0$ that is $d f\left(d \pi\left(X^{v}\right)\right)=0$ or equivalently we get $d(f \circ \pi)\left(X^{v}\right)=0$, that is $d(\tilde{\pi} \circ F)\left(X^{v}\right)=0\left(\bar{\pi}: T R^{2 n} \rightarrow R^{2 n}\right)$, which gives $d F\left(X^{v}\right) \in \operatorname{ker} d \tilde{\pi}=\overline{\mathfrak{V}}$.

Now we state the following results which are needed in our work.
Lemma 2.1. [3] Let $N$ be the unit normal vector field to the hypersurface $M$ of $R^{2 n}$ and $P=\left(p, X_{p}\right) \in T M$. Then the horizontal and vertical lifts $Y_{P}^{h}, Y_{P}^{c}$ of $Y_{p} \in T_{p} M$ satisfy

$$
d F_{P}\left(Y_{P}^{h}\right)=\left(d f_{p}\left(Y_{p}\right)\right)^{h}+V_{P}, \quad d F_{P}\left(Y_{P}^{v}\right)=\left(d f_{p}\left(Y_{p}\right)\right)^{v}
$$

where $V_{P} \in \mathfrak{V}_{P}$ is given by $V_{P}=\left\langle S_{p}\left(X_{p}\right), Y_{p}\right\rangle N_{P}^{v}, N_{P}^{v}$ being the vertical lift of the unit normal $N$ to with respect to the tangent bundle $\bar{\pi}: R^{4 n} \rightarrow R^{2 n}$.

Lemma 2.2. [3] If $(M, g)$ is an orientable hypersurface of $R^{2 n}$, and (TM, $\left.\bar{g}\right)$ is its tangent bundle as submanifold of $R^{4 n}$, then the metric $\bar{g}$ on $T M$ for $P=(p, u) \in T M$, satisfies:
(i) $\bar{g}_{P}\left(X_{P}^{h}, Y_{P}^{h}\right)=g_{p}\left(X_{p}, Y_{p}\right)+g_{p}\left(S_{p}\left(X_{p}\right), u\right) g_{p}\left(S_{p}\left(Y_{p}\right), u\right)$.
(ii) $\bar{g}_{P}\left(X_{P}^{h}, Y_{P}^{v}\right)=0$.
(ii) $\bar{g}\left(X^{v}, Y^{v}\right)=g_{p}\left(X_{p}, Y_{p}\right)$.

Remark 2.3. It is well known that a metric $\bar{g}$ defined on $T M$ using the Riemannian metric $g$ of $M$ (such as Sasaki metric, Cheeger-Gromoll metric) are
natural metrics in the sense that the submersion $\pi:(T M, \bar{g}) \longrightarrow(M, g)$ becomes a Riemannian submersion with respect to these metrics. However, as seen from above Lemmas, the induced metric on the tangent bundle $T M$ of a hypersurface $M$ of the Euclidean space $R^{2 n}$, as a submanifold of $R^{4 n}$ is not a natural metric because of the present of the term $g_{p}\left(S_{p}\left(X_{p}\right), u\right) g_{p}\left(S_{p}\left(Y_{p}\right), u\right)$ in the inner product of horizontal vectors on $T M$. Moreover, note that the for an orientable hypersurface $M$ of the Euclidean space $R^{2 n}$, the vertical lift $N^{v}$ of the unit normal is tangential to the submanifold $T M$ of $R^{4 n}$ as seen in 2.1

In what follows, we drop the suffixes like in $g_{p}\left(S_{p}\left(X_{p}\right), u\right)$ and and it will be understood from the context of the entities appearing in the equations.

Theorem 2.4. [3] Let $(M, g)$ be an orientable hypersurface of $R^{2 n}$, and $(T M, \bar{g})$ be its tangent bundle as submanifold of $R^{4 n}$. If $\nabla$ and $\bar{\nabla}$ denote the Riemannian connections on $(M, g)$ and $(T M, \bar{g})$ respectively, then
(i) $\bar{\nabla}_{X^{h}} Y^{h}=\left(\bar{\nabla}_{X} Y\right)^{h}-\frac{1}{2}(R(X, Y) u)^{v}$,
(ii) $\bar{\nabla}_{X^{v}} Y^{h}=g(S(X), Y) \circ \pi N^{v}$
(iii) $\bar{\nabla}_{X^{v}} Y^{v}=0, \quad(i v) \bar{\nabla}_{X^{h}} Y^{v}=\left(\bar{\nabla}_{X} Y\right)^{v}+g(S(X), Y) \circ \pi N^{v}$.

Lemma 2.5. [4] Let TM be the tangent bundle of an orientable hypersurface $M$ of $R^{2 n}$. Then for $X, Y \in \mathfrak{X}(M)$,
(i) $h\left(X^{v}, Y^{v}\right)=0$,
(ii) $h\left(X^{v}, Y^{h}\right)=0$,
(iii) $h\left(X^{h}, Y^{h}\right)=g(S(X), Y) \circ \pi N^{h}$.

Lemma 2.6. [4] For the tangent bundle $T M$ of an orientable hypersurface $M$ of $R^{2 n}$ and $X \in \mathfrak{X}(M)$, we have
(i) $\bar{D}_{X^{v}} N^{v}=0$,
(ii) $\bar{D}_{X^{v}} N^{h}=0$,
(iii) $\bar{D}_{X^{h}} N^{v}=-(S(X))^{v}$, (iv) $\bar{D}_{X^{h}} N^{h}=-(S(X))^{h}$.

Let $J$ be the natural complex structure on the Euclidean space $R^{2 n}$, which makes $\left(R^{2 n}, J,\langle\rangle,\right)$ a Kaehler manifold. Then on an orientable real hypersurface $M$ of $R^{2 n}$ with unit normal $N$, we define a unit vector field $\xi \in \mathfrak{X}(M)$ by $\xi=-J N$, with its dual 1-form $\eta(X)=g(X, \xi)$, where $g$ is the induced metric on $M$. For $X \in \mathfrak{X}(M)$, we express $J X=\varphi(X)+\eta(X) N$, where $\varphi(X)$ is the tangential component of $J X$, and it follows that $\varphi$ is a $(1,1)$ tensor field on $M$, and that $(\varphi, \xi, \eta, g)$ defines an almost contact metric structure on $M$ (cf. [5], [8], [9]), that is

$$
\varphi^{2} X=-X+\eta(X) \xi, \eta(\xi)=1, \eta \circ \varphi=0, \varphi(\xi)=0
$$

and

$$
g(\varphi X, \varphi Y)=g(X, Y)-\eta(X) \eta(Y), \quad X, Y \in \mathfrak{X}(M)
$$

Moreover, we have the following.

Lemma 2.7. [8] Let $M$ be an orientable real hypersurface of $R^{2 n}$. Then the structure $(\varphi, \xi, \eta, g)$ on $M$ satisfies
(i) $\left(\bar{\nabla}_{X} \varphi\right)(Y)=\eta(Y) S X-g(S X, Y) \xi$,
(ii) $\bar{\nabla}_{X} \xi=\varphi S X, X, Y \in \mathfrak{X}(M)$.

## 3. A Structure on $(T M, \bar{g})$

We know that the Euclidean space $R^{4 n}$ has many complex structures, however in this section we treat $R^{4 n}$ as the tangent bundle of $R^{2 n}$ and consider a specific complex structure on the Euclidean space $R^{4 n}$. Let $\bar{\pi}: R^{4 n}=$ $T R^{2 n} \rightarrow R^{2 n}$ be the submersion of the tangent bundle of $R^{2 n}$. Then it is easy to show that the Euclidean metric $\langle$,$\rangle on the tangent bundle R^{4 n}$ is Sasaki metric and using the canonical almost complex structure $J$ of $R^{2 n}$, we define $\bar{J}: \mathfrak{X}\left(R^{4 n}\right) \rightarrow \mathfrak{X}\left(R^{4 n}\right)$ by

$$
\bar{J}\left(E^{h}\right)=(J E)^{h}, \quad \bar{J}\left(E^{v}\right)=(J E)^{v}, \quad E \in \mathfrak{X}\left(R^{2 n}\right)
$$

and it is easily follows that $\bar{J}$ is an almost complex structure, satisfying $\langle\bar{J} E, \bar{J} F\rangle=\langle E, F\rangle$ with respect to the Euclidean metric $\langle$,$\rangle on R^{4 n}$ and that $\left(\bar{D}_{E} \bar{J}\right)(F)=0, E, F \in \mathfrak{X}\left(R^{4 n}\right)$ that is $\left(R^{4 n}, \bar{J},\langle\rangle,\right)$ is a Kaehler manifold. Regarding the complex structure $\bar{J}$ defined above, we have the following

Lemma 3.1. Let $\bar{\pi}: R^{4 n} \rightarrow R^{2 n}$ be the submersion of the tangent bundle $R^{4 n}=T R^{2 n}$. Then complex structure $\bar{J}$ on $R^{4 n}$ satisfies

$$
J \circ d \bar{\pi}=d \bar{\pi} \circ \bar{J}
$$

Proof. Take $X \in \mathfrak{X}\left(R^{2 n}\right)$, then for the horizontal lift $X^{h}$, we have:

$$
J \circ d \bar{\pi}\left(X^{h}\right)=J\left(d \bar{\pi}\left(X^{h}\right)\right)=J X \circ \bar{\pi}
$$

and

$$
d \bar{\pi} \circ \bar{J}\left(X^{h}\right)=d \bar{\pi}(J X)^{h}=J X \circ \bar{\pi}
$$

which proves

$$
J \circ d \bar{\pi}\left(X^{h}\right)=d \bar{\pi} \circ \bar{J}\left(X^{h}\right)
$$

Similarly for the vertical lift $X^{v}$ we have

$$
J \circ d \bar{\pi}\left(X^{v}\right)=J\left(d \bar{\pi}\left(X^{v}\right)\right)=0
$$

and

$$
d \bar{\pi} \circ \bar{J}\left(X^{v}\right)=d \bar{\pi}(J X)^{v}=0
$$

This proves the Lemma.
Remark 3.2. If $M$ is an orientable real hypersurface of the Euclidean space $R^{2 n}$ with immersion $f$, then $F=d f$ is the immersion of the tangent bundle $T M$ into the Euclidean space $R^{4 n}$ and as immersions are local embeddings, in general, we identify the local quantities on submanifold with those of the ambient space for instance we identify $d f(X)$ with $X$ for $X \in \mathfrak{X}(M)$. However,
while dealing with the immersion $F$ of $T M$ in $R^{4 n}$ one need to be cautious specially while dealing with the horizontal lifts (cf. 2.1). Therefore in what follows, we shall bring $d F$ in to play whenever it is needed specially in the case of horizontal lifts.

Observe that if $M$ is an orientable real hypersurface of the Euclidean space $R^{2 n}$ with unit normal vector field $N$, then we know that horizontal lift $N^{h}$ is a unit normal vector field to the submanifold $T M$ of $R^{4 n}$ and that the vertical lift $N^{v} \in \mathfrak{X}(T M)$ (cf.[1]). We have

$$
\begin{equation*}
\bar{J} N^{h}=(J N)^{h}=-(d f(\xi))^{h}=-d F\left(\xi^{h}\right)+g(S(\xi), u) N^{v} \in \mathfrak{X}(T M) \tag{3.1}
\end{equation*}
$$

and

$$
\begin{equation*}
\bar{J} N^{v}=(J N)^{v}=-\xi^{v} \in \mathfrak{X}(T M) \tag{3.2}
\end{equation*}
$$

Let $M$ be an orientable real hypersurface of the Kaehler manifold $\left(R^{2 n}, J,\langle\rangle,\right)$. Then as $T M$ is submanifold of the Kaehler manifold $\left(R^{4 n}, \bar{J},\langle\rangle,\right)$, we denote by $\Gamma\left(T^{\perp} T M\right)$ the space of smooth normal vector fields to $T M$. The restriction of the complex structure $\bar{J}$ on $R^{4 n}$ to $\mathfrak{X}(T M)$ and $\Gamma\left(T^{\perp} T M\right)$ can be expressed as

$$
\bar{J}(E)=\bar{\varphi}(E)+\bar{\psi}(E), \bar{J}(\bar{N})=\bar{G}(\bar{N})+\bar{\chi}(\bar{N}), \quad E \in \mathfrak{X}(T M), \bar{N} \in \Gamma\left(T^{\perp} T M\right)
$$

where $\bar{\varphi}(E), \bar{G}(\bar{N})$ are the tangential and $\bar{\psi}(E), \bar{\chi}(\bar{N})$ are the normal components of $\bar{J} E$, and $\bar{J}(\bar{N})$ respectively. Note that the horizontal lift $N^{h}$ of the unit normal $N$ to the hypersurface $M$ is normal to $T M$ that is $N^{h} \in \Gamma\left(T^{\perp} T M\right)$, where as the vertical lift $N^{v} \in \mathfrak{X}(T M)$.

Lemma 3.3. Let $T M$ be the tangent bundle of an orientable real hypersurface of $R^{2 n}$. Then for $X \in \mathfrak{X}(M)$,

$$
\begin{aligned}
& \bar{\varphi}\left(X^{h}\right)=(\varphi(X))^{h}-g(S(X), u) \xi^{v}, \quad \bar{\varphi}\left(X^{v}\right)=(\varphi(X))^{v}+\eta(X) \circ \pi N^{v} \\
& \bar{\psi}\left(X^{h}\right)=\eta(X) \circ \pi N^{h}, \quad \bar{\psi}\left(X^{v}\right)=0
\end{aligned}
$$

Proof. Note that for the horizontal lift $X^{h}$ we have

$$
\begin{aligned}
\bar{J} X^{h} & =\bar{J} d F\left(X^{h}\right)=\bar{J}\left((d f(X))^{h}+g(S X, u) \circ \pi N^{v}\right) \\
& =(J d f(X))^{h}+g(S X, u) \circ \pi(J N)^{v} \\
& =(\varphi X+\eta(X) N)^{h}-g(S X, u) \circ \pi \xi^{v} \\
& =(\varphi(X))^{h}-g(S X, u) \circ \pi \xi^{v}+\eta(X) \circ \pi N^{h}
\end{aligned}
$$

which together with the definition $\bar{J} X^{h}=\bar{\varphi}\left(X^{h}\right)+\bar{\psi}\left(X^{h}\right)$, on equating tangential and normal components give

$$
\bar{\varphi}\left(X^{h}\right)=(\varphi(X))^{h}-g(S(X), u) \xi^{v} \text { and } \bar{\psi}\left(X^{h}\right)=\eta(X) \circ \pi N^{h}
$$

Similarly for the vertical lift $X^{v}$, we have

$$
\bar{J} X^{v}=\bar{\varphi}\left(X^{v}\right)+\bar{\psi}\left(X^{v}\right)=(J X)^{v}=(\varphi X+\eta(X) N)^{v}
$$

which gives

$$
\left(\bar{\varphi}\left(X^{v}\right)\right)+\bar{\psi}\left(X^{v}\right)=(\varphi X)^{v}+\eta(X) \circ \pi N^{v}
$$

Comparing the tangential and normal components we conclude

$$
\bar{\varphi}\left(X^{v}\right)=(\varphi(X))^{v}+\eta(X) \circ \pi N^{v}, \quad \text { and } \quad \bar{\psi}\left(X^{v}\right)=0 .
$$

We choose a unit normal vector field $N^{*} \in \Gamma\left(T^{\perp} T M\right)$ such that $\left\{N^{*}, N^{h}\right\}$ is a local orthonormal frame of normals for the submanifold $T M$. It is known that $N^{*}$ is vertical vector field on the tangent bundle $R^{4 n}$ (cf. [1]). Since, $\left\langle\bar{J} N^{*}, N^{*}\right\rangle=0,\left\langle\bar{J} N^{*}, N^{h}\right\rangle=\left\langle N^{*}, \xi^{h}\right\rangle=0$, it follows that $\bar{J} N^{*} \in \mathfrak{X}(T M)$ and we define unit vector field $\zeta \in \mathfrak{X}(T M)$ by

$$
\begin{equation*}
\zeta=-\bar{J} N^{*} \tag{3.3}
\end{equation*}
$$

Now, for any normal vector field $\bar{N} \in \Gamma\left(T^{\perp} T M\right)$, we have

$$
\bar{N}=\left\langle\bar{N}, N^{*}\right\rangle N^{*}+\left\langle\bar{N}, N^{h}\right\rangle N^{h}
$$

which together with equations (3.1), (3.2) and (3.3) gives $\bar{\chi}(\bar{N})=0$ and that $\bar{J}(\bar{N}) \in \mathfrak{X}(T M)$, isgiven by

$$
\begin{equation*}
\bar{J}(\bar{N})=\langle\bar{J}(\bar{N}), \zeta\rangle \zeta+\langle\bar{J}(\bar{N}), T\rangle T \tag{3.4}
\end{equation*}
$$

where $T \in \mathfrak{X}(T M)$, is given by

$$
\begin{equation*}
T=\xi^{h}-g(S(\xi), u) N^{v}=-\bar{J} N^{h} \tag{3.5}
\end{equation*}
$$

Also, using equation (3.2), we have

$$
-\xi^{v}=\bar{J} N^{v}=\bar{\varphi}\left(N^{v}\right)+\bar{\psi}\left(N^{v}\right)
$$

which gives

$$
\begin{equation*}
\bar{\varphi}\left(N^{v}\right)=-\xi^{v} \text { and } \bar{\psi}\left(N^{v}\right)=0 \tag{3.6}
\end{equation*}
$$

Moreover, we have

$$
\begin{equation*}
\bar{\varphi}(\zeta)=0 \text { and } \bar{\psi}(\zeta)=N^{*}, \bar{\psi}\left(\xi^{h}\right)=N^{h} \tag{3.7}
\end{equation*}
$$

If we denote by $\alpha, \beta$ the smooth 1 -forms on $T M$ dual to the vector field $\zeta$ and $T$ respectively, then for $E \in \mathfrak{X}(T M)$, it follows that

$$
\bar{J}(\bar{\psi}(E))=-\alpha(E) \zeta-\beta(E) T
$$

and consequently, operating $\bar{J}$ on $\bar{J}(E)=\bar{\varphi}(E)+\bar{\psi}(E), E \in \mathfrak{X}(T M)$, we get

$$
\begin{equation*}
\bar{\varphi}^{2}=-I+\alpha \otimes \zeta+\beta \otimes T \text { and } \bar{\psi} \circ \bar{\varphi}=0 \tag{3.8}
\end{equation*}
$$

Using Lemma 2.1 and equations (3.3), (3.5), (3.6), (3.8), we see that the vector fields $\zeta, T$ and 1 -fomrs $\alpha, \beta$ satisfy

$$
\begin{equation*}
\bar{\varphi}(\zeta)=0, \bar{\varphi}(T)=0, \bar{g}(\zeta, T)=0, \alpha \circ \bar{\varphi}=0, \beta \circ \bar{\varphi}=0 \tag{3.9}
\end{equation*}
$$

Also, as $\bar{g}$ is the induced metric on the submanifold $T M$ and $\bar{J}$ is skew symmetric with respect to the Hermitian metric $\langle$,$\rangle , we have$

$$
\begin{equation*}
\bar{g}(\bar{\varphi}(E), F)=-\bar{g}(E, \bar{\varphi}(F)), \quad E, F \in \mathfrak{X}(T M) \tag{3.10}
\end{equation*}
$$

Then using equations (3.8), (3.9) and (3.10), we have

$$
\begin{equation*}
\bar{g}(\bar{\varphi}(E), \bar{\varphi}(F))=\bar{g}(E, F)-\alpha(E) \alpha(F)-\beta(E) \beta(F), \quad E, F \in \mathfrak{X}(T M) \tag{3.11}
\end{equation*}
$$

Thus we have proved the following
Lemma 3.4. Let TM be the tangent bundle of an orientable real hypersurface of $R^{2 n}$. Then there is a structure $(\bar{\varphi}, \zeta, T, \alpha, \beta, \bar{g})$ similar to contact metric structure on $T M$, where $\bar{\varphi}$ is a tensor field of type $(1,1), \zeta, T$ are smooth vector fields and $\alpha, \beta$ are smooth 1 -forms dual to $\zeta, T$ with respect to the Riemannian metric $\bar{g}$ satisfying

$$
\begin{gathered}
\bar{\varphi}^{2}=-I+\alpha \otimes \zeta+\beta \otimes T, \bar{\varphi}(\zeta)=0, \bar{\varphi}(T)=0, \alpha \circ \bar{\varphi}=0, \beta \circ \bar{\varphi}=0, \bar{g}(\zeta, T)=0 \\
\bar{g}(\bar{\varphi}(E), \bar{\varphi}(F))=\bar{g}(E, F)-\alpha(E) \alpha(F)-\beta(E) \beta(F), \quad E, F \in \mathfrak{X}(T M)
\end{gathered}
$$

In the next Lemma, we compute the co-variant derivatives of the tensor $\bar{\varphi}$.
Lemma 3.5. Let $(\bar{\varphi}, \zeta, T, \alpha, \beta, \bar{g})$ be the structure on the tangent bundle TM of an orientable real hypersurface $M$ of the Euclidean space $R^{2 n}$. Then
(i) $\left(\bar{\nabla}_{X^{h}} \bar{\varphi}\right)\left(Y^{h}\right)=\left\{\left(\nabla_{X} \varphi\right)(Y)\right\}^{h}-\{X(g(S Y, u)+g(S Y, u) J S X)\}^{v}$
(ii) $\left(\bar{\nabla}_{X^{n}} \bar{\varphi}\right)\left(Y^{v}\right)=0$,
(iii) $\left(\bar{\nabla}_{X^{v}} \bar{\varphi}\right)\left(Y^{v}\right)=0,\left(\bar{\nabla}_{X^{v}} \bar{\varphi}\right)\left(Y^{h}\right)=g(S X, \varphi Y) \circ \pi N^{v}+g(S X, Y) \circ \pi \xi^{v}$.

Proof. Using the definition of $\bar{J}$, Lemma 2.1 and Lemma 3.3 together with equation (3.1), we get for $X, Y \in \mathfrak{X}(M)$

$$
\begin{aligned}
\bar{J} Y^{h} & =\bar{J} d F\left(Y^{h}\right)=\bar{J}\left((d f(Y))^{h}+g(S Y, u) \circ \pi N^{v}\right) \\
& =(\varphi Y+\eta(Y) N)^{h}-g(S Y, u) \circ \pi \xi^{v} \\
& =\bar{\varphi}\left(Y^{h}\right)+\eta(Y) \circ \pi N^{h}
\end{aligned}
$$

which gives

$$
\begin{aligned}
\bar{D}_{X^{h}} \bar{J} Y^{h}= & \bar{D}_{\left((d f(X))^{h}+g(S X, u) \circ \pi N^{v}\right)}\left(\bar{\varphi}\left(Y^{h}\right)+\eta(Y) \circ \pi N^{h}\right) \\
= & \bar{D}_{(d f(X))^{h}} \bar{\varphi}\left(Y^{h}\right)+X(\eta(Y)) \circ \pi N^{h}+\eta(Y) \circ \pi \bar{D}_{(d f(X))^{h}} N^{h} \\
& +g(S X, u) \circ \pi \bar{D}_{N^{v}}\left((\varphi(Y))^{h}-g(S(Y), u) \circ \pi \xi^{v}\right)+0 \\
& +g(S X, u) \circ \pi \eta(Y) \circ \pi \bar{D}_{N^{v}} N^{h}
\end{aligned}
$$

Note that the tangent bundle $T R^{2 n}=R^{4 n}$ has Sasaki metric and thus using Lemma 7.2 of [10] (keeping in view that $R^{2 n}$ is flat), in the above equation, we get

$$
\begin{equation*}
\bar{D}_{X^{h}} \bar{J} Y^{h}=\bar{\nabla}_{X^{h}} \bar{\varphi}\left(Y^{h}\right)+h\left(X^{h}, \bar{\varphi}\left(Y^{h}\right)+X(\eta(Y)) \circ \pi N^{h}-\eta(Y) \circ \pi(S X)^{h}\right. \tag{3.12}
\end{equation*}
$$

Similarly we have

$$
\begin{align*}
\overline{J D}_{X^{h}} Y^{h}= & \bar{J}\left(\bar{D}_{\left((d f(X))^{h}+g(S X, u) \circ \pi N^{v}\right)}\left((d f(Y))^{h}+g(S Y, u) \circ \pi N^{v}\right)\right) \\
= & \bar{J}\left\{\bar{\nabla}_{X^{h}} Y^{h}+h\left(X^{h}, Y^{h}\right)+X\left(g(S Y, u) \circ \pi N^{v}+g(S Y, u) \circ \pi\left(D_{X} N\right)^{v}\right.\right. \\
& \left.+g(S X, u) \circ \pi \bar{D}_{N^{v}}(d f Y)^{h}+0+0\right\} \\
= & \bar{\varphi}\left(\bar{\nabla}_{X^{h}} Y^{h}\right)+\bar{\psi}\left(\bar{\nabla}_{X^{h}} Y^{h}\right)+\bar{J} h\left(X^{h}, Y^{h}\right)-X\left(g(S Y, u) \circ \pi \xi^{v}\right. \\
& -g(S Y, u) \circ \pi \bar{J}(S X)^{v} \\
= & \bar{\varphi}\left(\bar{\nabla}_{X^{h}} Y^{h}\right)+\bar{\psi}\left(\bar{\nabla}_{X^{h}} Y^{h}\right)-g(S X, Y) \circ \pi \xi^{h}-X\left(g(S Y, u) \circ \pi \xi^{v}\right. \\
& -g(S Y, u) \circ \pi(\varphi S X)^{v}-g(S Y, u) \circ \pi \eta(S X) N^{v}(3.13) \tag{3.13}
\end{align*}
$$

where we used Lemmas 2.3, 2.4 and Lemma 7.2 in [10]. Now as $\left(R^{4 n}, \bar{J},\langle\rangle,\right)$ is a Kaehler manifold, the equations (3.12) and (3.13) on comparing tangential we get

$$
\left(\bar{\nabla}_{X^{h}} \bar{\varphi}\right)\left(Y^{h}\right)=\left\{\left(\nabla_{X} \varphi\right)(Y)\right\}^{h}-\{X(g(S Y, u)+g(S Y, u) J S X)\}^{v}
$$

which proves (i).

Now, using $h\left(X^{v}, Y^{v}\right)=0$ and $\bar{S}_{\bar{\psi}\left(Y^{v}\right)} X^{v}=0$ together with $\bar{D}_{X^{v}} \bar{J} Y^{v}=$ $\overline{J D}_{X^{v}} Y^{v}$, and comparing tangential components, we immediately arrive at

$$
\left(\bar{\nabla}_{X^{v}} \bar{\varphi}\right)\left(Y^{v}\right)=0
$$

Next, we have $\bar{\nabla}_{X^{v}} \bar{\varphi}\left(Y^{h}\right)=\bar{\nabla}_{X^{v}}\left((\varphi Y)^{h}-g(S X, u) \circ \pi \xi^{v}\right)=\bar{\nabla}_{X^{v}}(\varphi Y)^{h}=$ $g(S X, \varphi Y) \circ \pi N^{v}$ and $\bar{\varphi}\left(\bar{\nabla}_{X^{v}} Y^{h}\right)=g(S X, \varphi Y) \circ \pi \bar{\varphi}\left(N^{v}\right)=-g(S X, Y) \circ \pi \xi^{v}$. Thus, we get

$$
\left(\bar{\nabla}_{X^{v}} \bar{\varphi}\right)\left(Y^{h}\right)=g(S X, \varphi Y) \circ \pi N^{v}+g(S X, Y) \circ \pi \xi^{v}
$$

Finally, using $h\left(X^{h}, Y^{v}\right)=0$ and $\bar{S}_{\bar{\psi}\left(Y^{v}\right)} X^{h}=0$ together with $\bar{D}_{X^{h}} \bar{J} Y^{v}=$ $\overline{J D}_{X^{h}} Y^{v}$, and comparing tangential components, we immediately arrive at

$$
\left(\bar{\nabla}_{X^{h}} \bar{\varphi}\right)\left(Y^{v}\right)=0
$$

Lemma 3.6. Let $(\bar{\varphi}, \zeta, T, \alpha, \beta, \bar{g})$ be the structure on the tangent bundle TM of an orientable real hypersurface $M$ of the Euclidean space $R^{2 n}$. Then for $E \in \mathfrak{X}(T M)$,

$$
\begin{array}{ll}
\bar{\nabla}_{E} \zeta=\bar{\varphi}\left(\bar{S}_{N^{*}}(E)\right)-\bar{J}\left(\bar{\nabla}_{E}^{\perp} N^{*}\right), & h(E, \zeta)=\bar{\psi}\left(\bar{S}_{N^{*}}(E)\right) \\
\bar{\nabla}_{E} T=\bar{\varphi}\left(\bar{S}_{N^{h}}(E)\right)-\bar{J}\left(\bar{\nabla}_{E}^{\perp} N^{h}\right), & h(E, T)=\bar{\psi}\left(\bar{S}_{N^{h}}(E)\right)
\end{array}
$$

Proof. Using equation (2.2), we have

$$
\begin{aligned}
\bar{\nabla}_{E} \zeta & =\bar{D}_{E} \zeta-h(E, \zeta) \\
& =-\bar{J}_{E} N^{*}-h(E, \zeta) \\
& =\bar{J}\left(\bar{S}_{N^{*}}(E)\right)-\bar{J}\left(\bar{\nabla}_{E}^{\perp} N^{*}\right)-h(E, \zeta) \\
& =\bar{\varphi}\left(\bar{S}_{N^{*}}(E)\right)+\bar{\psi}\left(\bar{S}_{N^{*}}(E)\right)-\bar{J}\left(\bar{\nabla}_{E}^{\perp} N^{*}\right)-h(E, \zeta)
\end{aligned}
$$

Since $\bar{J}(\bar{N}) \in \mathfrak{X}(T M)$ for each normal $\bar{N} \in \Gamma\left(T^{\perp} T M\right)$, equation tangential and normal components in above equation, we get the first part. The second part follows similarly using $T=-\bar{J} N^{h}$.

Now, we prove the following:
Theorem 3.7. The tangent bundle TM of an orientable real hypersurface $M$ of the Euclidean space $R^{2 n}$ is a CR-submanifold of the Kaehler manifold $\left(R^{4 n}, \bar{J},\langle\rangle,\right)$.

Proof. Use the structure $(\bar{\varphi}, \zeta, T, \alpha, \beta, \bar{g})$ on the submanifold $T M$ of $R^{4 n}$ to define the distribution $D$ by

$$
D=\{E \in \mathfrak{X}(T M): \alpha(E)=\beta(E)=0\}
$$

and $D^{\perp}$ be the distribution spanned by the orthogonal vector fields $\zeta$ and $T$. Note that $\zeta$ is unit vector field on $T M$ and the length of the vector field $T$ satisfies

$$
\|T\|^{2}=1+2 g(S(\xi), u)^{2} \geq 1
$$

which shows that $D^{\perp}$ is 2-dimensional distribution on $T M$ and that $\bar{J} D^{\perp}=$ $\Gamma\left(T^{\perp} T M\right)$. It is easy to see that $D$ and $D^{\perp}$ are orthogonal complementary distributions and that $\operatorname{dim} D=4(n-1)$. Note that for $E \in \mathfrak{X}(T M)$, we have

$$
\bar{\psi}(E)=\left\langle\bar{\psi}(E), N^{*}\right\rangle N^{*}+\left\langle\bar{\psi}(E), N^{h}\right\rangle N^{h}=\alpha(E) N^{*}+\beta(E) N^{h}
$$

and consequently if $E \in D$, then above equation gives $\bar{J} E=\bar{\varphi} E$ which is orthogonal to both $\zeta$ and $T$ and that $\bar{J} E \in D$, which implies $\bar{J} D=D$. This proves that $T M$ is a CR-submanifold of the Kaehler manifold $\left(R^{4 n}, \bar{J},\langle\rangle,\right)(\mathrm{cf}$. [8]).

## 4. Killing Vector Fields on $T M$

Let $T M$ be the tangent bundle of an orientable real hypersurface $M$ of the Euclidean space $R^{2 n}$. Recall that a vector field $\varsigma \in \mathfrak{X}(T M)$ on the Riemannian manifold $(T M, \bar{g})$ is said to be Killing if

$$
\left(£_{\varsigma} \bar{g}\right)(E, F)=0, \quad E, F \in \mathfrak{X}(T M)
$$

where $£_{\varsigma}$ is the Lie derivative with respect to the vector field $\varsigma$. We have seen in previous section that the tangent bundle $(T M, \bar{g})$ admits a structure $(\bar{\varphi}, \zeta, T, \alpha, \beta, \bar{g})$, that is similar to the almost contact structure. In this section
we are interested in finding conditions under which the special vector fields $\zeta$ and $T$ are Killing vector fields and as a particular case we get that the tangent bundle $\left(T S^{2 n-1}, \bar{g}\right)$ of the unit sphere $S^{2 n-1}$ in the Euclidean space $R^{2 n}$ admits a nontrivial Killing vector field.

Theorem 4.1. Let $(\bar{\varphi}, \zeta, T, \alpha, \beta, \bar{g})$ be the structure on the tangent bundle TM of an orientable real hypersurface $M$ of the Euclidean space $R^{2 n}$. Then the vector field $\zeta$ is Killing.

Proof. First note that on taking inner product with $N^{*}$ in each part of Lemma 2.5 , we conclude that $\bar{S}_{N^{*}}\left(X^{h}\right)=0, \bar{S}_{N^{*}}\left(X^{v}\right)=0, X \in \mathfrak{X}(M)$ and consequently,

$$
\begin{equation*}
\bar{S}_{N^{*}}(E)=0, \quad E \in \mathfrak{X}(T M) \tag{4.1}
\end{equation*}
$$

Also using second part of equation (2.2) in (ii) and (iv) of Lemma 2.4, we conclude that $\bar{\nabla}_{E}^{\perp} N^{h}=0, E \in \mathfrak{X}(T M)$, that is $N^{h}$ is parallel on the normal bundle of $T M$. Moreover, we have

$$
\bar{\nabla}_{E}^{\perp} N^{*}=\left\langle\bar{\nabla}_{E}^{\perp} N^{*}, N^{h}\right\rangle N^{h}=-\left\langle N^{*}, \bar{\nabla}_{E}^{\perp} N^{h}\right\rangle N^{h}=0
$$

that is $N^{*}$ is parallel in the normal bundle of $T M$. Thus using equation (4.1) in Lemma 3.5 , it follows that $\zeta$ is a parallel vector field and consequently, it is a Killing vector field.

Theorem 4.2. Let $(\bar{\varphi}, \zeta, T, \alpha, \beta, \bar{g})$ be the structure on the tangent bundle TM of an orientable real hypersurface $M$ of the Euclidean space $R^{2 n}$. Then the vector field $T$ is Killing if and only if the following condition holds

$$
\bar{g}\left(\left(\bar{\varphi} \circ \bar{S}_{N^{h}}-\bar{S}_{N^{h}} \circ \bar{\varphi}\right)\left(X^{h}\right), Y^{h}\right)=0, \quad X, Y \in \mathfrak{X}(M)
$$

Proof. Since $N^{h}$ is parallel in the normal bundle of $T M$, by Lemma 3.5, we have

$$
\begin{equation*}
\bar{\nabla}_{E} T=\bar{\varphi}\left(\bar{S}_{N^{h}}(E)\right), \quad E \in \mathfrak{X}(T M) \tag{4.2}
\end{equation*}
$$

Also using Lemma 2.4, we conclude that

$$
\begin{equation*}
\bar{S}_{N^{h}}\left(X^{v}\right)=0, \bar{S}_{N^{h}}\left(X^{h}\right)=(S(X))^{h}, \quad X \in \mathfrak{X}(M) \tag{4.3}
\end{equation*}
$$

Then using skew-symmetry of the tensor $\bar{\varphi}$, and equations (4.2) and (4.3) together with Lemma 3.3, we immediately arrive at

$$
\begin{gather*}
\left(£_{T} \bar{g}\right)\left(X^{v}, Y^{v}\right)=0  \tag{4.4}\\
\left(£_{T} \bar{g}\right)\left(X^{h}, Y^{v}\right)=\bar{g}\left(\bar{\varphi} \circ \bar{S}_{N^{h}}\left(X^{h}\right), Y^{v}\right)=-\bar{g}\left(\bar{S}_{N^{h}}\left(X^{h}\right), \bar{\varphi}\left(Y^{v}\right)\right) \\
=-\bar{g}\left(\bar{S}_{N^{h}}\left(X^{h}\right),(\varphi(Y))^{v}+\eta(X) \circ \pi N^{v}\right)=0 \\
\left(£_{T} \bar{g}\right)\left(X^{h}, Y^{h}\right)=\bar{g}\left(\left(\bar{\varphi} \circ \bar{S}_{N^{h}}-\bar{S}_{N^{h}} \circ \bar{\varphi}\right)\left(X^{h}\right), Y^{h}\right) \tag{4.6}
\end{gather*}
$$

and the equations (4.4)-(4.6) prove the Theorem.

Consider the unit sphere $S^{2 n-1}$ in the Euclidean space $R^{2 n}$, whose shape operator is given by $S=-I$. Using Lemma 2.4, we get on the tangent bundle $T S^{2 n-1}$ that

$$
\bar{S}_{N^{h}}\left(X^{h}\right)=(S(X))^{h}=-X^{h}, \quad \bar{S}_{N^{h}}\left(X^{v}\right)=0
$$

Then the Lemma 3.3 together with above equation, gives

$$
\begin{aligned}
\left(\bar{\varphi} \circ \bar{S}_{N^{h}}-\bar{S}_{N^{h}} \circ \bar{\varphi}\right)\left(X^{h}\right) & =-\bar{\varphi}\left(X^{h}\right)-\bar{S}_{N^{h}}\left((\varphi(X))^{h}-g(S(X), u) \circ \pi \xi^{v}\right) \\
& =-g(X, u) \circ \pi \xi^{v}, \quad X \in \mathfrak{X}\left(S^{2 n-1}\right)
\end{aligned}
$$

and consequently,

$$
\bar{g}\left(\left(\bar{\varphi} \circ \bar{S}_{N^{h}}-\bar{S}_{N^{h}} \circ \bar{\varphi}\right)\left(X^{h}\right), Y^{h}\right)=0, \quad X, Y \in \mathfrak{X}\left(S^{2 n-1}\right)
$$

Thus as a particular case of the Theorem 4.2, we have
Corollary 4.3. Let $(\bar{\varphi}, \zeta, T, \alpha, \beta, \bar{g})$ be the structure on the tangent bundle $T S^{2 n-1}$ of the unit sphere $S^{2 n-1}$ in the Euclidean space $R^{2 n}, n>1$. Then the vector field $T$ is a nontrivial Killing vector field.

Proof. It remains to be shown that $T$ is nontrivial. Since, $N^{h}$ is parallel in the normal bundle of $T S^{2 n-1}$, by Lemmas 2.4 and 3.5, we have

$$
\begin{equation*}
\bar{\nabla}_{X^{h}} T=-\bar{\varphi}\left(X^{h}\right), \quad X \in \mathfrak{X}\left(S^{2 n-1}\right) \tag{4.7}
\end{equation*}
$$

where we used the fact that the shape operator $S$ of the unit sphere $S^{2 n-1}$ is given by $S=-I$. The Lemma 3.4 gives the rank of $\bar{\varphi}$ is $4(n-1)$ and consequently, equation (4.7) gives that the Killing vector field $T$ is not parallel, that is $T$ is a nontrivial Killing vector field.
